## Best Reverser Write-Up: Analyzing Uncommon Firmware

While developing tasks for PHDays' contest in reverse engineering, we had a purpose of replicating real problems that RE specialists might face. At the same time we tried to avoid allowing cliché solutions.

Let us define what common reverse engineering tasks look like. Given an executable file for Windows (or Linux, MacOS or any other widely-used operating system). We can run it, watch it in a debugger, and twist it in virtual environments in any way possible. File format is known. The processor's instruction set is x86, AMD64 or ARM. Library functions and system calls are documented. The equipment can be accessed through the operating system only. Using tools like IDAPro and HexRays makes analysis of such applications very simple, while debug protection, virtual machines with their own instruction sets, and obfuscation could complicate the task. But large vendors hardly ever use any of those in their programs. So there's no point in developing a contest aimed at demonstrating skills that are rarely addressed in practice.

However, there's another area, where reverse engineering became more in-demand, that's firmware analysis. The input file (firmware) could be presented in any format, can be packed, encrypted. The operating system could be unpopular, or there could be no operating system at all. Parts of the code could not be changed with firmware updates. The processor could be based on any architecture. (For example, IDAPro "knows" not more than 100 different processors.) And of course, there's no documentation available, debugging or code execution cannot be performed—a firmware is presented, but there's no device.

Our contest's participants needed to analyze an executable file and find the correct key and the relative

TESTIMONY ON HOW I GOT MY LOAN FROM A GENUINE LOA...

TESTIMONY ON HOW I GOT MY LOAN FROM A GENUINE LOA...

i just want to share my experience with everyone. ...

email (any internet user was able to take part in the contest).

## Part One: Loader

At the first stage, the input file is an ELF file compiled with a cross compiler for the PA-RISC architecture. IDA can work with this architecture, but not as good as with x86. Most requests to stack variables are not identified automatically, and you'll have to do it manually. At least you can see all the library functions (log, printf, memcpy, strlen, fprintf, scanf, memset, strstr) and even symbolic names for some functions (c32, exk, cry, pad, dec, cen, dde). The program expects two input arguments: an email and key.

```
.text:002013E0      ldo          0xE0(%r19), %r25 # .LC8 # ". Usage: %s <email> <key>\n"
.text:002013E4      copy
.text:002013E8      call        _fprintf
```

It's  
not

hard to figure out that the key should consist of two parts separated by the “-” character. The first part should consist of seven MIME64 characters (0-9A-Za-z+/), the second part of 32 hex characters that translate to 16 bytes.

```
.text:002014A0      ldo          0x114(%r19), %r25 # .LC10 # "%02x"
.text:002014A4      copy
.text:002014A8      call        _scanf
```

Further we can see calls to c32 functions that result in:

```
t = c32(-1, argv[1], strlen(argv[1])+1)
k = ~c32(t, argv[2], strlen(argv[2])+1)
```

Name of the function is a hint: it's a CRC32 function, which is confirmed by the constant 0xEDB88320.

Next, we call the dde function (short for doDecrypt), and it receives the inverted output of the CRC32 function (encryption key) as the first argument, and the address and the size of the encrypted array as the second and third ones.

Decryption is performed by BTEA (block tiny encryption algorithm) based on the code taken from Wikipedia. We can guess that it's BTEA from the use of the constant DELTA=0x9E3779B9. It's also used in other algorithms on which BTEA is based on, but there are not many of them.

The key should be of 128-bit width, but we receive only 32 bits from CRC32. So we get three more DWORDs from the exk function (expand\_key) by multiplying the previous value by the same DELTA.

However, the use of BTEA is uncommon. First of all, the algorithm supports a variable-width block size, and we use a block of 12-bytes width (there are processors that have 24-bit width registers and memory, then why should we use only powers of two). And in the second place, we switched encryption and decryption functions.

Since data stream is encrypted, cipher block chaining is applied. Entropy is calculated for decrypted data in the cen function (calc\_entropy). If its value exceeds 7, the decryption result is considered incorrect and the program will exit.

The encryption key is 32-bit width, so it seems to be easily brute-forced. However, in order to check every key we need to decrypt 80 kilobytes of data, and then calculate entropy. So brute-forcing the encryption key will take a lot of time.

But after the calculation, we call the pad function (strip\_pad), which check and remove PKCS#7 padding. Due to CBC features, we need to decrypt only one block (the last one), extract N byte, check whether its range is between 1 and 12 (inclusive) and each of the last N bytes has value N. This allows reducing the number of operations needed to check one key. But if the last encrypted byte equals 1 (which is true for 1/256 keys), the check should be still performed.

The faster method is to assume that decoded data have a DWORD-aligned length (4 bytes). Then in the last DWORD of the last block there may be only one of three possible values: 0x04040404, 0x08080808 or 0x0C0C0C0C. By using heuristic and brute force methods you can run through all possible keys and find the right one in less than 20 minutes.

If all the checks after the decryption (entropy and the integrity of the padding) are successful, we call the fire\_second\_proc function, which simulates the launch of the second CPU and the loading of decrypted data of the firmware (modern devices usually have more than one processor—with different architectures).

If the second processor launches, it receives the user's email and 16 bytes with the second part of the key via the function send\_auth\_data. At this point we made a mistake: there was the size of the string with the email instead of the size of the second part of the key.

## Part Two: Firmware

The analysis of the second part is a little bit more complicated. There was no ELF file, only a memory image—without headings, function names, and other metadata. Type of the processor and load address were unknown as well.

We thought of brute force as the algorithm of determining the processor architecture. Open in IDA, set the following type, and repeat until IDA shows something similar to a code. The brute force should lead to the conclusion that it is big-endian SPARC.

Now we need to determine the load address. The function 0x22E0 is not called, but it contains a lot of code. We can assume that is the entry point of the program, the start function.

In the third instruction of the start function, an unknown library function with one argument == 0x126F0 is called, and the same function is called from the start function four more times, always with arguments with similar values (0x12718, 0x12738, 0x12758, 0x12760). And in the middle of the program, starting from 0x2490, there are five lines with text messages:

```
00002490      .ascii "Firmware loaded, sending ok back."<0>
000024B8      .ascii "Failed to retrieve email."<0>
000024D8      .ascii "Failed to retrieve codes."<0>
000024F8      .ascii "Gratz!"<0>
00002500      .ascii "Sorry may be next time..."<0>
```

Assuming that the load address equals 0x126F0-0x2490 == 0x10260, then all the arguments will indicate the lines when calling the library function, and the unknown function turns out to be the printf function (or puts).

After changing the load base, the code will look something like this:

```
ROM:00012540      save    %sp, -0x2F8, %sp
ROM:00012544      set     aFirmwareLoaded, %00 ? "Firmware loaded, sending ok back."
ROM:0001254C      call   puts
ROM:00012550      nop
ROM:00012554      set     0x0A0B0AB0, %00
ROM:0001255C      call   sub_12194
ROM:00012560      nop
ROM:00012564      add     %fp, var_108, %g1
ROM:00012568      mov     %g1, %00
ROM:0001256C      mov     0, %01
ROM:00012570      mov     0x101, %02
ROM:00012574      call   sub_24064
ROM:00012578      nop
ROM:0001257C      add     %fp, var_210, %g1
ROM:00012580      mov     %g1, %00
ROM:00012584      mov     0, %01
ROM:00012588      mov     0x101, %02
ROM:0001258C      call   sub_24064
ROM:00012590      nop
ROM:00012594      add     %fp, var_108, %g1
ROM:00012598      mov     %g1, %00
ROM:0001259C      call   sub_121BC
ROM:000125A0      nop
ROM:000125A4      mov     %00, %g1
ROM:000125A8      cmp     %g1, -1
ROM:000125AC      bne     loc_125CC
ROM:000125B0      nop
ROM:000125B4      set     aFailedToRetrie, %00 ? "Failed to retrieve email."
ROM:000125BC      call   puts
```

The

value of 0x0A0B0AB0, transmitted to the function sub\_12194, can be found in the first part of the task, in the function fire\_second\_proc, and is compared with what we obtain from read\_pipe\_u32 (). Thus sub\_12194 should be called write\_pipe\_u32.

Similarly, two calls of the library function sub\_24064 are memset (someVar, 0, 0x101) for the email and code, while sub\_121BC is read\_pipe\_str (), reversed write\_pipe\_str () from the first part.

The first function (at offset 0 or address 0x10260) has typical constants of MD5\_Init:

Next to the call to MD5\_Init, it is easy to detect the function MD5\_Update () and MD5\_Final (), preceded by the call to the library strlen ().

```

Not  
too

many unknown functions are left in the start() function.

The sub\_12480 function reverses the byte array of specified length. In fact, it's memrev, which receives a code array input of 16 bytes.

Obviously, the sub\_24040 function checks whether the code is correct. The arguments transfer the calculated value of MD5(email), the array filled in function sub\_12394, and the number 16. It could be a call to memcmp!

The real trick is happening in sub\_12394. There is almost no hints there, but the algorithm is described by one phrase—the multiplication of binary matrix of the 128 by the binary vector of 128. The matrix is stored in the firmware at 0x240B8.

Thus, the code is correct if MD5(email) == matrix\_mul\_vector (matrix, code).

**Calculating the Key**

To find the correct value of the code, you need to solve a system of binary equations described by the matrix, where the right-hand side are the relevant bits of the MD5(email). If you forgot linear algebra: this is easily solved by Gaussian elimination.

If the right-hand side of the key is known (32 hexadecimal characters), we can try to guess the first seven characters so that the CRC32 calculation result was equal to the value found for the key BTEA. There are about 1024 of such values, and they can be quickly obtained by brute-force, or by converting CRC32 and checking valid characters.

Now you need to put everything together and get the key that will pass all the checks and will be recognized as valid by our verifier :)

We were afraid that no one would be able to solve the task from the beginning to the end. Fortunately, Victor Alyushin showed that our fears were groundless. You can find his write-up on the task at <http://nightsite.info/blog/16542-phdays-2015-best-reverser.html>. This is the second time Victor Alyushin has won the contest (he was the winner in 2013 as well).

A participant who wished to remain anonymous solved a part of the task and took second place.

Thanks to all participants!

HACK ATM AND BECOME RICH TODAY  
How to hack an ATM MACHINE or BANK ACCOUNT  
You can hack and break into a bank's security ATM Machine without carrying guns or any weapon.  
How is this possible? First of all we have to learn about the manual hacking of ATM MACHINES and BANKING ACCOUNTS HOW THE ATM MACHINE WORKS. If you have been to the bank you find out that the money in the ATM MACHINE is being filled right inside the house where the machine is built with enough security.to hack this machine We have develop the special blank ATM Card which you can use in any ATM Machine around the world. this card is been programmed and can withdraw 2000 USD within 24 hours in any currency your country make use of. The card will make the security camera malfunction at that particular time until you are done with the transaction you can never be trace. getting the card you will forward the company your address details so we can proceed to send the card to you once you agree to the terms and conditions. you can

#### TESTIMONY ON HOW I WAS RESCUED BY A GOD-SENT LENDER..

Hello everyone, am writing this Testimony because am really grateful for what Mason Diego did for me and my family, when I thought there was no hope he came and make my family feel alive again by lending us loan at a very low interest rate of 2%. Well I have been searching for a loan to settle my debts for the past three months all I met scammed and took my money until I finally met a God sent Lender. I never thought that there are still genuine loan lenders on the internet but to my greatest surprise i got my loan without wasting much time so if you are out there looking for a loan of any amount i would advise you to email Mr Diego via: { diegolocompany@yahoo.com } and be free of internet scams. thanks... Kathie Roper from California, USA.

Reverse engineering and re engineering concepts work well with the people who are technically well versed and who can crack any technical issue like a jack. More challenges are in the way of data organization where software like hadoop helps a lot. I came to know about the reverse engineering when I was attending a course at [hadoop training in hyderabad](#)

GET RICH IN LESS THAN 3DAYS

It all depends on how fast you can be to get the new PROGRAMMED blank ATM card that is capable of hacking into any ATM machine, anywhere in the world. I got to know about this BLANK ATM CARD when I was searching for job online about a month ago..It has really changed my life for good and now I can say I'm rich and I can never be poor again. The least money I get in a day with it is about \$50,000.(fifty thousand USD) Every now and then I keeping pumping money into my account. Though is illegal, there is no risk of being caught ,because it has been programmed in such a way that it is not traceable, it also has a technique that makes it impossible for the CCTV to detect you..For details on how to get yours today, email the hackers on : (oceancardhackers@gmail.com ). Tell your loved once too, and start to live large. That's the simple testimony of how my life changed for good...Love you all ...contact them now, the email address again is : oceancardhackers@gmail.com

or call +2348168199202

CHI YOUNG TECH of the email address. (chiyoungtechworld@gmail.com) its at it again! Cool way to have financial freedom!!! Are you tired of living a poor life, then here is the opportunity you have been waiting for. Get the new ATM BLANK CARD that can hack any ATM MACHINE and withdraw money from any account. You do not require anybody's account number before you can use it. Although you and I knows that its illegal, there is no risk using it. It has SPECIAL FEATURES, that makes the machine unable to detect this very card, and its transaction is can't be traced . You can use it anywhere in the world. With this card, you can withdraw nothing less than \$50,000 in a day. So to get the card, reach the hackers via email address : chiyoungtechworld@gmail.com.
